Theoretical Photochemistry WiSe 2017/18

Lecture 3

Irene Burghardt (burghardt@chemie.uni-frankfurt.de)

 $http://www.theochem.uni-frankfurt.de/teaching/ \longrightarrow Theoretical Photochemistry$

Topics

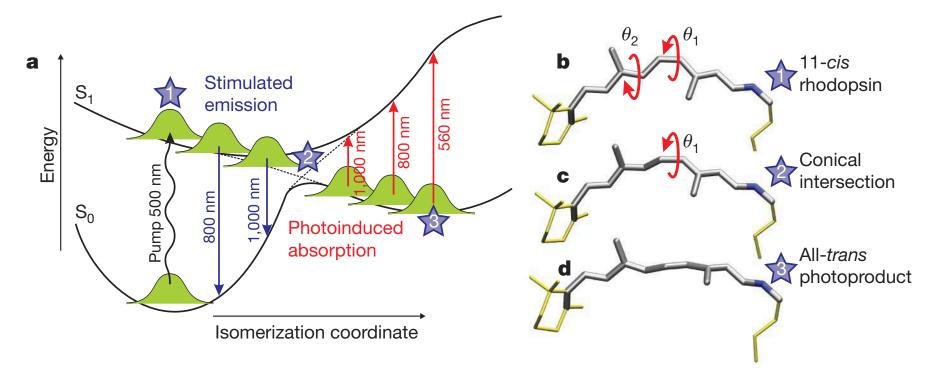

- **1. Photophysical Processes**
- 3. Wavepackets
- 5. The Franck-Condon picture of electronic transitions
- 6. What do we measure experimentally?
- 2. The Born-Oppenheimer approximation
- 4. Beyond Born-Oppenheimer non-adiabatic transitions
- 7. Conical intersections
- 8. Examples: Ethene, Protonated Schiff Bases (Retinal), Azobenzene
- 9. Some electronic structure aspects
- **10.** Dynamics: trajectories or wavefunctions?
- **11.** Wavefunction propagation techniques

- 12. Trajectory surface hopping techniques
- 13. Non-linear optical spectroscopy: calculation of spectroscopic signals
- 14. Extended systems: Excitons, light-harvesting, etc.
- **15. Solvent/environmental effects**

Literature

Non-adiabatic wavepacket motion

Polli et al., Nature 467, 440 (2010)

• example: isomerisation of retinal

Coupled BO surfaces: matrix notation

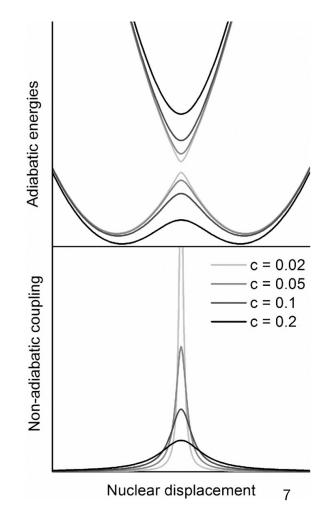

$$i\hbarrac{\partial}{\partial t}\left(egin{array}{c} \chi_1(R,t)\ \chi_2(R,t)\end{array}
ight) \ = \ \left(egin{array}{c} \hat{T}_N+\epsilon_1(R) & \hat{\Lambda}_{12}(R)\ \hat{\Lambda}_{21}(R) & \hat{T}_N+\epsilon_2(R)\end{array}
ight)\left(egin{array}{c} \chi_1(R,t)\ \chi_2(R,t)\end{array}
ight)$$

- non-diagonal representation of the nuclear kinetic energy operator
- diagonal representation of the potential operator (which follows from the fact that the ϵ_n 's are eigenvalues of the electronic Schrödinger Equation)

Non-adiabatic coupling at an "avoided crossing"

The non-adiabatic coupling becomes very large at a so-called avoided crossing

This is because the character of the electronic wavefunction changes very rapidly

"Diabatic" representation

• unitary transformation of electronic wavefunctions such that the kinetic energy couplings (almost) vanish,

 $\Phi^{
m dia}(\mathrm{r}_{
m el}|oldsymbol{R})=oldsymbol{S}(oldsymbol{R})oldsymbol{\psi}^{
m ad}(\mathrm{r}_{
m el}|oldsymbol{R})$

• in turn, a potential type coupling appears:

• in practice, one often prefers to work with a diabatic representation, since the diabatic states have a well-defined electronic character, and the calculation of derivative couplings is avoided

Diabatic representation: matrix notation

$$i\hbarrac{\partial}{\partial t}\left(egin{array}{c} ilde{\chi}_1(R,t)\ ilde{\chi}_2(R,t)\end{array}
ight) \ = \ \left(egin{array}{c} \hat{T}_N+V_1(R) & oldsymbol{V}_{12}(R)\ oldsymbol{V}_{12}(R)\ oldsymbol{V}_{12}(R)\end{array}
ight) \left(egin{array}{c} ilde{\chi}_1(R,t)\ oldsymbol{V}_{21}(R) & \hat{T}_N+V_2(R)\end{array}
ight) \left(egin{array}{c} ilde{\chi}_1(R,t)\ oldsymbol{\chi}_2(R,t)\end{array}
ight)$$

$$egin{aligned} &= \left[\left(egin{array}{ccc} \hat{T}_N & 0 \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \ & \$$

- diagonal representation of the nuclear kinetic energy operator
- non-diagonal representation of the potential (i.e., diabatic electronic wavefunctions are *not* eigenfunctions of the electronic Hamiltonian!)
- if we diagonalize the diabatic potential matrix, we get the *adiabatic* energies back

Example: dissociation of Nal

1200

1200

200

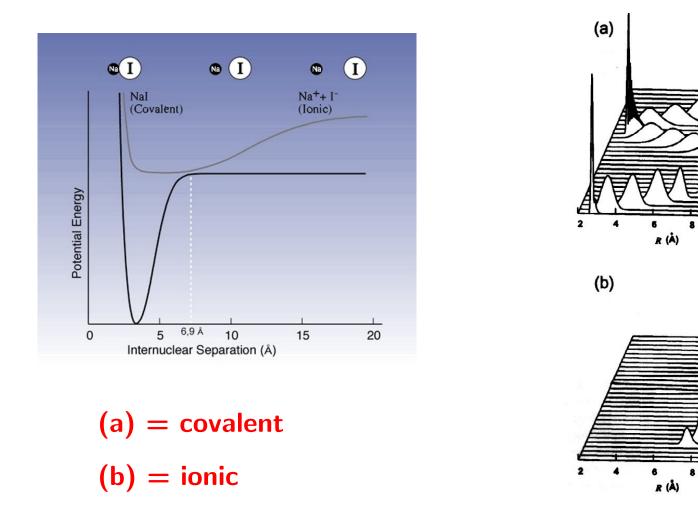

400 ^f (fs)

ROO

400 ^(fs)

10

10

• in this case, the dynamics is "almost" adiabatic on the upper BO surface

Diabatic representations – some more detail

• Is it always possible to define the adiabatic-to-diabatic transformation?

$$\psi^{
m dia}(r_{
m el},R)=S(R)\psi^{
m ad}(r_{
m el},R)$$

in such a way that the non-adiabatic (kinetic-energy) coupling $\hat{\Lambda}_{nm}$ is eliminated. Here,

$$\hat{\Lambda}_{nm} = -rac{\hbar^2}{2M}igg(F_{nm}rac{\partial}{\partial R}+G_{nm}igg)$$

$$F_{nm} = \ \langle \psi^{
m ad}_m(r_{
m el},R) | rac{\partial}{\partial R} \psi^{
m ad}_n(r_{
m el},R)
angle \ ; \ G_{nm} = \ \langle \psi^{
m ad}_m(r_{
m el},R) | rac{\partial^2}{\partial R^2} \psi^{
m ad}_n(r_{
m el},R)
angle$$

Analysis shows that

 a strictly diabatic basis does not exist, except for special cases (diatomics, "isolated 2-state system" in polyatomics)

Mead & Truhlar, J. Chem. Phys. 77, 6090 (1982)

Quasi-diabatic representations

construct (non-unique) bases which approximately eliminate the $\hat{\Lambda}_{nm}$

• e.g., work with an "isolated two-state system assumption"

 argue that the divergent part of the derivative couplings originates in the direct coupling between the two states

 in addition, only the lowest-order terms in a Taylor expansion around the intersection cause the divergence

Thiel, Köppel, J. Chem. Phys. 110, 9371 (1999)

• in general: quasi-diabatic bases are smooth w.r.t. molecular properties (e.g., dipole moments)

• for polar solvation problems: define charge-localized ("VB-type") diabatic states
